Because of some difficulties for recruitment during the first sessions of the study, the inclusion criteria are modified as:

- The number of previous episodes of bronchiolitis is no more limited to one: second episodes of bronchiolitis can be included, since three episodes of bronchiolitis in the same winter are needed to diagnose an infant asthma.
- Children aged 3 to 24 months can now be included (previously 12 months).

These changes don’t have any impact on the information, the consent, the process, the execution (investigators, centres), the methodology and the statistical analyses, since they are non-substantial.
