<table>
<thead>
<tr>
<th>Rationale and Background:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The interferon-free combination regimen of paritaprevir/r – ombitasvir with or without dasabuvir (ABBVIE REGIMEN) ± ribavirin (RBV) for the treatment of chronic hepatitis C (CHC) has been shown to be safe and effective in randomized controlled clinical trials with strict inclusion and exclusion criteria under well controlled conditions.</td>
</tr>
<tr>
<td>The ABBVIE REGIMEN is expected to be first available in the Netherlands for the treatment of CHC in 2015.</td>
</tr>
<tr>
<td>The rationale for this observational study is to determine how the efficacy and safety of the ABBVIE REGIMEN as demonstrated in pivotal trials translates into real world everyday clinical settings, which means evaluating its effectiveness. Whereas efficacy can be defined as a measure of the capacity of a treatment to produce the desired effect in a controlled environment, such as in a randomized controlled trial, effectiveness is the extent to which a drug achieves its intended effect in the usual clinical setting. Effectiveness trials typically have limited exclusion criteria and will involve the broader patient populations in routine clinical practice and per local label which might include patients with heterogeneous compliance patterns and patients with significant comorbid conditions and could be used to model and disseminate best practices. Effectiveness research allows for external patient-, provider-, and system-level factors and can therefore be more relevant for health-care decisions by both providers in practice and policy-makers.</td>
</tr>
<tr>
<td>This observational study is the first effectiveness research examining the ABBVIE REGIMEN ± RBV, used according to local label, under real world conditions the Netherlands in a clinical practice patient population.</td>
</tr>
<tr>
<td>The label of the ABBVIE REGIMEN ± RBV will vary according to hepatitis C virus (HCV) genotype/subtype and stage of liver disease. It is therefore relevant to understand the pattern of use and outcome in daily clinical practice. In addition, this study will provide data on the impact of adherence on treatment outcomes in everyday settings, which may help treating physicians to improve the management of patients under their care.</td>
</tr>
<tr>
<td>The aim of this observational study is to provide evidence of the effectiveness, tolerability, adherence, healthcare resource utilization, and quality of life and work productivity of the ABBVIE REGIMEN ± RBV in a real world setting across clinical practice patient populations treated in The Netherlands.</td>
</tr>
</tbody>
</table>

<tbody>
<tr>
<td>Assessing the effectiveness of the interferon-free regimen of Paritaprevir/r – Ombitasvir, ± Dasabuvir, ± Ribavirin in patients with CHC in a real life setting across clinical practice patient populations.</td>
</tr>
</tbody>
</table>
Primary Objective

1. To describe in routine clinical practice the effectiveness of the interferon-free ABBVIE REGIMEN ± RBV in patients with CHC as evidenced by sustained virological response at 12 weeks after end of treatment (SVR12)

Secondary Objectives

1. To describe the pattern of real world use of the ABBVIE REGIMEN ± RBV with respect to different patient and treatment characteristics.
2. To evaluate the influence of adherence on treatment outcome in routine clinical practice.
3. To describe the tolerability of the ABBVIE REGIMEN ± RBV.
4. To document the effect of the ABBVIE REGIMEN ± RBV on PROs and work productivity in the Dutch population.
5. To determine the impact of the ABBVIE REGIMEN ± RBV on healthcare resource utilization.

Study Design:

This is a prospective, multi-center observational study in patients receiving the interferon-free ABBVIE REGIMEN ± RBV.

The prescription of a treatment regimen is at the discretion of the physician in accordance with local clinical practice and label, is made independently from this observational study and precedes the decision to offer the patient the opportunity to participate in this study.

Target Population:

Patients are eligible for observation in this cohort if the following applies:

- Treatment-naïve or -experienced adult male or female patients (age ≥ 18 yrs) with confirmed CHC, genotype 1 or 4, receiving combination therapy with the interferon-free ABBVIE REGIMEN ± RBV according to standard of care and in line with the current local label.
- If RBV is co-administered with the ABBVIE REGIMEN, it has been prescribed in line with the current local label (with special attention to contraception requirements and contraindication during pregnancy).
- Patients must be able to speak and understand the Dutch language at such a level that they can understand and sign the informed consent and be able to understand and complete the questionnaires without any external help.
- Patients must voluntarily sign and date informed consent prior to inclusion into the study.

Patients are not eligible for observation in this cohort if the following applies:

- Patients participating or intending to participate in a concurrent interventional therapeutic trial.
- Patients who are unable to complete the questionnaires due to cognitive impairment or lack of any kind of cognitive competence, as to be judged by the healthcare professional who is treating the patient
- Patients who are unable to complete the questionnaires due to language incompetence
- Patients who are unable to voluntarily sign and date the informed consent
- Patients included for treatment who do not meet the treatment criteria as described in the current local label

**Variables:**

**Primary Variable**
- The percentage of patients achieving SVR12 (HCV RNA <50 IU/mL 12 weeks [i.e. ≥70 days] after the last actual dose of the ABBVIE REGIMEN)

**Secondary Variables**
- Type of treatment regimen (± Dasabuvir, ± RBV, intended and actual combination, dose and duration)
- Adherence
  - Percentage of the DAA dose taken in relation to the target dose of DAA (cumulative dose taken divided by target dose in percent)
  - Percentage of the RBV dose taken in relation to the target dose of RBV (cumulative dose taken divided by target dose in percent)
  - Percentage of missed RBV treatment days in relation to the target number of RBV treatment days
- Serious and non-serious adverse events and pregnancy occurrences
- Questionnaires on PROs: EuroQol 5 dimension 5 level (EQ-5D-5L) questionnaire, work productivity and activity impairment (WPAI) questionnaire prior to treatment initiation, at EoT as well as 12 and 24 weeks after EoT
- Questionnaire on healthcare resource utilization

**Data Sources:**
Source documents are defined as original documents. The investigator will document patient data in his/her own patient files which will serve as source data for the study.

**Study Size:**
The sample size of the study is not based on statistical considerations. It is expected that 50-55 patients can be enrolled.

**Data Analysis:**
The core population (CP) is defined as all patients of the target population (TP) (definition see above), who have started the treatment combination recommended in the current local label for their disease characteristics. Patients not receiving the treatment recommended in the local label will be summarized in the non-core population (NCP). In addition, the core population with sufficient follow-up data (CPSFU) is defined as all CP patients, who have (i) evaluable HCV RNA data ≥70 days after the last actual dose of the ABBVIE REGIMEN or (ii) a HCV RNA value
≥50 IU/mL at the last measurement or (iii) had HCV RNA <50 IU/mL at the last measurement, but no HCV RNA measurement ≥70 days after the last actual dose of the ABBVIE REGIMEN due to reasons related to safety (e.g. dropped out due to adverse event) or incomplete efficacy information (e.g. virologic failure such as relapse is reported in the electronic case report form (eCRF) but date and value of the corresponding HCV RNA test is missing). The safety population (SP) is defined as all patients who received at least one dose of the ABBVIE REGIMEN.

Descriptive and exploratory statistical methods will be used to analyze the data of the study. All baseline and disease characteristics will be summarized for the CP stratified by the CP analysis groups (based on genotype 1 subtype, fibrosis status, treatment experienced or naïve), which are relevant for scheduled treatment combination (± dasabuvir, ± RBV) and duration (12 or 24 weeks). In addition, baseline summaries will be repeated for the SP and TP without stratification into subgroups. Further details of analysis populations and the CP analysis groups will be specified in the statistical analysis plan (SAP).

The primary effectiveness analysis will be performed for CP patients, stratified by the CP analysis groups. Response rates (i.e. SVR12 rate, end of treatment [EoT] response rate, relapse rate, viral breakthrough) will be determined for the various CP analysis groups. The relapse rates will be estimated in patients of the CP analysis groups with EoT response and sufficient HCV RNA measurements post treatment. Viral breakthrough rates will be estimated in all patients of the CP analysis groups, who have at least one undetectable HCV RNA measurement on treatment and at least one on-treatment or EoT measurement thereafter. For all rates specified above 95%-confidence intervals (CIs) will be determined using the Wilson’s Score method.

All safety variables will be summarized for patients in the SP using descriptive statistical methods stratified by the type of combination treatment and scheduled treatment duration.

Confidential Information
No use or disclose outside AbbVie is permitted without prior written authorization from AbbVie

5.0 Amendments and Updates

- July 2017: study size and statistical analysis updated for total inclusion of 50-55 patients, instead of originally expected 255 patients.
- February 2018: SVR48 data points removed as this is no longer standard of care in the Netherlands.

6.0 Milestones

- Start of Data Collection: November 2015
- End of Data Collection: April 2018
- Final Report of Study Results: January 2019

7.0 Rationale and Background

7.1 Background

Infection with the hepatitis C virus (HCV) is associated with considerable morbidity and mortality [1] and is a leading cause of chronic liver disease, cirrhosis, and hepatocellular carcinoma (HCC), as well as the most common indication for liver transplantation in many countries [2]. Around 60-85% of subjects exposed to HCV do not clear the virus and go on to develop chronic disease [3] [4]. Chronic hepatitis C (CHC) affects an estimated 2-3% of the world’s population - equaling approximately 130-210 million individuals [5] [6]. The prevalence varies markedly from one geographic area to another ranging from 0.1-1% in Western Europe to 1-2% in Latin America and up to 4.9% in some regions of Eastern Europe [8] [9] [10].

HCV demonstrates a high degree of genetic variability and has been classified into seven major genotypes (and a large number of subtypes) the distribution of which varies globally [11]. Genotypes 1 through 3 are found worldwide; the other genotypes have a more restricted distribution, genotype 4 is found predominantly in the Middle East, Central Africa, and Egypt; genotype 5 in South Africa; and genotype 6 mainly in Asia. HCV genotypes 1a and 1b are the most common forms, accounting for 60% of HCV infections worldwide [12] [13] [14] [15].

HCV is primarily transmitted by parenteral exposures to contaminated blood, most frequently by injection drug use, exposures in health-care settings and inadequate
infection-control practices (tattoo, piercing). Occupational, perinatal and sexual exposure can also result in transmission of HCV [16] [17]. Since the early 1990’s routine blood screening protocols have been introduced in most countries and as a consequence transmission of the virus is rarely seen following receipt of blood, blood products or through organ transplants.

The natural course of CHC leads to progressive fibrosis and can eventually lead to cirrhosis of the liver over the course of 20-30 years in approximately 15-30% of infected individuals [18]. Once patients become cirrhotic, around 6% per year are expected to develop hepatic decompensation (ascites, encephalopathy, variceal hemorrhage, hepatorenal syndrome, or hepatic synthetic dysfunction) and around 3% per year will develop HCC [19]. Over the same time frame, between 4 and 5% of patients can be expected to require liver transplantation or die [19] [20]. Progression is not necessarily a linear process and can be accelerated by a number of factors including the age of the patient, duration of HCV infection, male gender, alcohol consumption and co-infection with other viruses such as hepatitis B virus (HBV) and human immunodeficiency virus (HIV) [4] but also by concomitant steatosis and obesity. Comorbid conditions can impact CHC treatment eligibility, safety, tolerability and efficacy of therapy [21] [22].

The burden of advanced liver disease varies widely across countries and is dependent upon several factors including chronic HCV prevalence and age distribution (and duration of infection) of those infected [23]. Due to an aging cohort of patients and an associated increase in the incidence of severe liver disease, the burden of CHC will continue to increase. In persons 30–49 years of age, the prevalence of the disease is 3–fold higher than in other age groups. By 2020, the rates of HCC and liver-related deaths among individuals with CHC are expected to increase by 81% and 180%, respectively [24].

The eradication of the virus, defined as the absence of HCV ribonucleic acid (RNA) in serum (as shown by a sensitive test) at the end of treatment (EoT) and 12-24 weeks later (sustained virological response [SVR]), is the therapeutic goal of CHC treatment [25] [26] [27] and is generally accepted as a virological cure, thus, eventually preventing the aforementioned complications [26] [27].

Achieving an SVR was associated with significant reduction in all-cause death compared to patients who did not achieve SVR (5-year mortality rate in HCV genotype 1-infected patients: 6.7% vs 14.4%, respectively) [28]. In another study the 10-year cumulative all-cause mortality rate was 8.9% in patients with SVR and 26.0% without SVR (p<0.001), the liver-related mortality or transplantation was 1.9% with SVR and 27.4% without SVR (p<0.001), the rate of HCC was 5.1% with and 21.8% without SVR (p<0.001), and the rate of patients experiencing liver failure was 2.1% with and 29.9% (p<0.001) without
SVR [29]. Patients with SVR following treatment with pegylated interferon (pegIFN) with or without RBV have also shown improvement in liver histology and a reduction in liver-related death in several studies [30] [31] [32]. Moreover, patients with compensated cirrhosis who achieve SVR essentially eliminate their subsequent risk of decompensation, may achieve histologic regression, and decrease their risk of HCC by two-thirds [33] [34] [35].

In the 1980’s and 1990’s interferon alfa was the first drug to show activity against HCV. However, the effectiveness of interferon monotherapy in the treatment of CHC infection was generally unsatisfactory resulting in an overall SVR rate across genotypes of <20% [36] [37]. Combination therapy with interferon plus ribavirin (RBV) improved SVR rates but still overall rates across genotypes remained below 50% [38] [39]. Following the introduction of long-acting interferons (peginterferon alfa-2a and peginterferon alfa-2b [i.e. pegIFNs]) in combination with RBV more than a decade ago, further advances have been made in efficacy with overall rates of SVR up to 54-63% [39] [40] [41]. SVR rates vary substantially by HCV genotype with genotype 1 being the most difficult-to-treat, thus requiring longer treatment periods to obtain SVR with interferon-based dual therapy. SVR rates up to around 50% can be achieved in patients with genotype 1 whereas for genotypes 2 and 3 cure rates of up to 80% can be achieved [41].

Treatment with pegIFN and RBV is associated with considerable, often treatment-limiting toxicities including cytopenias, neuro-psychiatric disorders and influenza-like symptoms.

In 2011 the first direct-acting antivirals (DAAs), specifically the protease inhibitors boceprevir and telaprevir, have been approved by the US Food and Drug Administration (FDA) and the European Medicines Agency (EMA) for treatment of HCV genotype 1. These first generation DAAs have significantly improved efficacy with rates of SVR reported as high as 63-75% among treatment-naïve HCV genotype 1 individuals [42] [43] [44]. However, these DAAs must be used in combination with pegIFN and RBV as triple combination therapy and the tolerability profile is further impaired by additional DAA specific adverse effects such as rash, pruritus, dysgeusia and anemia [42] [43] [44]. Treatment regimens with these DAAs are rather complicated with the necessity of futility rules and a response guided therapy duration of up to 48 weeks in selected patients.

Since 2014 the new standard of care for genotype 1 is pegIFN and RBV combined with either the nonstructural protein 3/nonstructural protein 4A (NS3/4A) protease inhibitor simeprevir or the nucleotide nonstructural protein 5B (NS5B) polymerase inhibitor sofosbuvir [45] [46].
Simeprevir is a NS3/4A protease inhibitor which was approved by the FDA at the end of 2013 and by the EMA in May 2014. In the phase III studies QUEST 1 and 2 treatment-naïve patients with genotype 1 yielded SVR rates of 80%, around 90% of these patients were eligible for truncated therapy of 24 weeks in a response guided treatment setting [47] [48]. Very similar results were reported for patients with prior relapse in the PROMISE trial [49]. In the ATTAIN study 771 treatment-experienced partial and null-responder patients were randomized to either simeprevir plus pegIFN and RBV or telaprevir plus pegIFN and RBV. Although efficacy rates were similar (SVR was 55% and 54%, respectively) the safety profile of simeprevir was significantly improved, in particular with regards to anemia (13% vs. 37%) and pruritus (31% vs. 43%), while serious adverse events (SAEs) were reported by 2% and 9% of patients, respectively [50]. Notably, among patients infected with HCV genotype 1a the presence of a common Q80K polymorphism (pre-existing resistance-associated variant or not) results in significantly reduced response rates and thus, it is recommended that patients infected with HCV genotype 1a are screened for this mutation, and if the respective variant is present, consideration is given to selecting an alternative therapy [51].

Sofosbuvir acts as an RNA chain terminator within the catalytic site of the NS5B polymerase. It was approved by the FDA in December 2013 and by the EMA in January 2014 for treatment of genotype 1, 4, 5, and 6 along with pegIFN plus RBV and in genotype 2 and 3 patients as an interferon-free regimen with RBV only.

In the NEUTRINO phase III trial with sofosbuvir plus pegIFN/RBV in 326 treatment-naïve genotype 1, 4, 5 and 6 patients, the overall SVR was 90% (92% in genotype 1a and 82% in genotype 1b; 80% in cirrhotic patients) with a tolerability profile similar to pegIFN plus RBV. One further advantage of this triple treatment regimen is the treatment duration of just 12 weeks [52].

Data on the interferon-free combination of sofosbuvir plus RBV in treatment-naïve patients with genotype 1 are only available from small trials and results are somewhat inconsistent. When given for a duration of 24 weeks SVR rates of 50-68% have been reported and this regimen is currently only recommended for patients who cannot take pegIFN [45] [46] [53] [54].

Thus, currently available approved treatment regimens are not optimal for many patients and there is a clear unmet need for effective anti-HCV compounds which can increase the likelihood of successful treatment and/or decrease the need for pegIFN as components of CHC therapy, ideally with shorter treatment duration.
Combinations of multiple DAAs targeting different steps of viral replication have the potential to significantly improve CHC treatment compared to current therapies by increasing SVR rates, eliminating interferon as a component of therapy, increasing the safety and tolerability of treatment, shortening duration of therapy and simplifying the treatment algorithm. In addition, wider application of DAA therapy and better responses with combination DAA regimens could significantly reduce the public health burden of this disease.

AbbVie’s interferon-free regimen for the treatment of CHC includes 3 DAAs targeting different steps in HCV replication. Paritaprevir is a NS3/4A protease inhibitor with nanomolar potency \textit{in vitro} and is co-administered with low-dose ritonavir, an inhibitor of the cytochrome P-450 enzyme CYP3A4. As a pharmacologic enhancer of paritaprevir, ritonavir co-administration with paritaprevir (paritaprevir \textit{r}) results in higher drug exposures than administration of paritaprevir alone [55]. Ombitasvir (ABT-267) is a nonstructural protein 5A (NS5A) inhibitor with picomolar potency \textit{in vitro}, and dasabuvir (ABT-333) is a NS5B non-nucleoside polymerase inhibitor with nanomolar potency \textit{in vitro}.

The 3 DAA combination of paritaprevir \textit{r} – ombitasvir plus dasabuvir with or without RBV has been initially evaluated in 6 Phase III studies with genotype 1 infected patients (SAPPHIRE-I [56], SAPPHIRE-II [57], PEARL-II [58], PEARL-III [59], PEARL-IV [59], TURQUOISE-II [60]).

Therapy for 12 weeks with the above regimen in non-cirrhotic patients resulted in the following SVR rates 12 weeks after EoT (SVR12):

\begin{table}[h]
\centering
\begin{tabular}{|l|l|l|l|}
\hline
Population and treatment duration & Genotype & SVR12 & SVR12 \\
& & ABBVIE REGIMEN + RBV & ABBVIE REGIMEN alone \\
\hline
Non-cirrhotic, treatment-naïve (12 weeks) & 1a & 95-97\% \textit{(SAPPHIRE-I, PEARL-IV)} & 90\% \textit{(PEARL-IV)} \\
& 1b & 98-99.5\% \textit{(SAPPHIRE-I, PEARL-III)} & 99\% \textit{(PEARL-III)} \\
\hline
Non-cirrhotic, treatment-experienced (12 weeks) & 1a & 96\% \textit{(SAPPHIRE-II)} & n.a. \\
& 1b & 97\% \textit{(SAPPHIRE-II, PEARL-II)} & 100\% \textit{(PEARL-II)} \\
\hline
\end{tabular}
\caption{SVR12 rates in clinical trials}
\end{table}
These results suggest that the ABBVIE REGIMEN with RBV is the optimal regimen for genotype 1a infected patients, while patients with genotype 1b do not require RBV.

The TURQUOISE-II [60] study explored the efficacy of the ABBVIE REGIMEN in the traditionally most difficult-to-treat cirrhotic patients. This large study enrolled exclusively genotype 1 infected patients with cirrhosis, including treatment-naïve and treatment-experienced individuals. All patients received the ABBVIE REGIMEN with RBV and were randomized to 12 or 24 weeks of therapy. Overall 92% and 96% of patients achieved SVR following treatment for 12 or 24 weeks, respectively. Analysis of subgroups demonstrated that the small difference in SVR between treatment arms was due largely to the subgroup of genotype 1a treatment-experienced prior null responders treated for 12 weeks who achieved an SVR of 80%. This subgroup of patients achieved an SVR of 93% when treated for 24 weeks. Among genotype 1a infected patients, partial responders and relapers had higher SVR rates than null responders in the 12 week treatment group, while similar SVR rates were seen among the null responders, partial responders and relapers treated for 24 weeks, suggesting that the longer duration of 24 weeks is required only for cirrhotic genotype 1a null responders. SVR rates were very high across all subgroups in genotype 1b treatment-experienced patients treated for 12 and 24 weeks.

The ABBVIE REGIMEN has been studied with and without RBV in over 2,300 patients in Phase III trials across a variety of patient populations including those with compensated cirrhosis. Based on Phase III data, the ABBVIE REGIMEN, with or without RBV, was well tolerated with a low discontinuation rate. Adverse events (AEs) were typically mild, and many of the AEs and laboratory abnormalities reported were attributable to the presence of RBV. However, these AEs were much milder than observed when RBV was given in combination with interferon. Transient, asymptomatic serum alanine aminotransferase (ALT) elevations were observed at a low rate, were not associated with hepatic dysfunction and generally resolved with ongoing treatment. A disproportionate number of the cases were in women on concurrent ethinyl estradiol-containing therapy (i.e., contraceptives or hormone replacement) and discontinuation of the hormonal therapy with continuation or brief interruption of the ABBVIE REGIMEN led to resolution in serum ALT elevation. Transient elevations in serum bilirubin (predominantly indirect) were observed in subjects receiving the ABBVIE REGIMEN with RBV, related to the inhibition of the bilirubin transporters, organic anion-transporting polypeptides (OATPs) 1B1/1B3, by paritaprevir and RBV-induced hemolysis. Bilirubin elevations occurred after initiation of treatment, peaked by study Week 1, and generally resolved with ongoing therapy.
Bilirubin elevations were not associated with aminotransferase elevations. The frequency of indirect bilirubin elevations was lower among subjects who did not receive RBV.

Response of CHC genotype 4 was assessed in the phase II study PEARL-I in which 86 treatment-naive patients were randomized to the 2 DAA combinations of paritaprevir/r–ombitasvir with vs. without RBV for 12 weeks. The SVR was 100% with RBV vs. 91% without RBV [61]. No serious SAEs or AEs leading to discontinuation were reported.

These results from pivotal studies are encouraging and the new interferon-free regimens might provide physicians with the armamentarium to cure the vast majority of patients infected with CHC. However, the medical community is expecting data which show how these results translate into routine clinical practice particularly after the experience with the first protease inhibitors which were available to physicians and where the outcome in everyday life and especially the tolerability was far less favorable in certain difficult-to-treat patient subgroups than expected from the development trials [62] [63].

7.2 Rationale

The ABBVIE REGIMEN ± RBV for the treatment of CHC has been shown to be safe and effective in randomized controlled clinical trials with strict inclusion and exclusion criteria under well controlled conditions.

The ABBVIE REGIMEN is expected to be first available in the Netherlands for the treatment of CHC in 2015.

The rationale for this observational study is to determine how the efficacy and safety of the ABBVIE REGIMEN as demonstrated in pivotal trials translates into real world everyday clinical settings, evaluating its effectiveness. Whereas efficacy can be defined as a measure of the capacity of a treatment to produce the desired effect in a controlled environment, such as in a randomized controlled trial, effectiveness is ‘the extent to which a drug achieves its intended effect in the usual clinical setting’ [64]. Effectiveness trials typically have limited exclusion criteria and will involve the broader patient populations in routine clinical practice, treated per local label, which might include patients with heterogeneous compliance patterns and patients with significant comorbid conditions and could be used to model and disseminate best practices. Effectiveness research allows for external patient-, provider-, and system-level factors and can therefore be relevant for health-care decisions by both providers in practice and policy-makers [65].
This observational study is the first effectiveness research examining the ABBVIE REGIMEN ± RBV, used according to local label, under real world conditions in the Netherlands in clinical practice patient population.

During the last decade when dual therapy with pegIFN plus RBV was standard of care for the treatment of CHC, management of patients and clinical outcome were improved following the discovery of predictive factors of virological response, often in observational studies with large data bases [66]. Thus treatment could be targeted to patients most likely to respond and futile treatment stopped in patients with a low likelihood of virological cure. HCV genotype and subtype, baseline viral load, fibrosis stage, age, treatment exposure and on-treatment virological response proved to be useful predictors for the eradication of HCV in everyday clinical practice [27]. The discovery of a genetic disposition of the Interleukin 28B (IL28B) single nucleotide polymorphism (SNP) contributed further to our understanding of virological responses to PegIFN and RBV regimen [67]. For new interferon-free treatment regimens knowledge of predictive factors of virological response is extremely sparse and several of the now well established predictors of response were not initially identified through analyses of the development trials. This observational study may play an important part in bridging the data gaps and could help identify predictive factors of virological response in everyday clinical settings which were not detected in interventional trials and which could be used to further optimize treatment with the interferon-free ABBVIE REGIMEN in the future.

The label of the ABBVIE REGIMEN will vary according to HCV genotype/subtype and stage of liver disease. It is therefore relevant to understand the pattern of use and outcome in daily clinical practice. In addition, this study will provide data on the impact of adherence on treatment outcomes in everyday settings, which may help treating physicians to improve the management of patients under their care.

The aim of this observational study is to provide evidence of the effectiveness, tolerability, adherence, healthcare resource utilization, quality of life and work productivity of the ABBVIE REGIMEN ± RBV in a real world setting across clinical practice patient populations.
8.0 Research Question and Objectives

8.1 Research Question

What is the effectiveness, tolerability, adherence, healthcare resource utilization, quality of life and work productivity of the interferon-free ABBVIE REGIMEN ± RBV in patients with CHC in a real life setting across clinical practice patient populations?

8.2 Objectives

8.2.1 Primary Objective

1. To describe in routine clinical practice the effectiveness of the interferon-free ABBVIE REGIMEN ± RBV in patients with CHC as evidenced by SVR12

8.2.2 Secondary Objectives

1. To describe the pattern of real world use of the ABBVIE REGIMEN ± RBV with respect to different patient and treatment characteristics
2. To evaluate the influence of adherence on treatment outcome in routine clinical practice
3. To describe the tolerability of the ABBVIE REGIMEN ± RBV
4. To document the effect of the ABBVIE REGIMEN ± RBV on PROs and work productivity in the Dutch population
5. To determine the impact of the ABBVIE REGIMEN ± RBV on healthcare resource utilization

9.0 Research Methods

9.1 Study Design

This is a prospective, multi-center observational study in patients receiving the interferon-free ABBVIE REGIMEN with or without RBV. The prescription of a treatment regimen is at the discretion of the physician in accordance with local clinical practice and label, is made independently from this observational study and precedes the decision to offer the patient the opportunity to participate in this study.

Adult patients chronically infected with HCV, receiving the interferon-free ABBVIE REGIMEN will be offered the opportunity to participate in this study during a routine clinical visit at the participating sites.
After written informed consent has been obtained, patient data including demographic data, HCV disease characteristics, co-morbidities, co-medication, treatment details, and laboratory assessments as recorded in the patient's medical records (source documentation) will be documented in the electronic case report form (eCRF). Patients will be observed for the duration of the ABBVIE REGIMEN therapy and for up to 24 weeks after treatment completion. No patient identifiable information will be captured, a unique patient number will be automatically allocated by the web based eCRF system once the investigator or designee creates a new patient file.

This study is focusing on collecting real-world data. Follow-up visits, treatment, procedures and diagnostic methods will follow physicians’ routine clinical practice. The observational study period entails the following data collection schemes, data documented will be those closest to the time windows as indicated in Figure 1:

- 12-week treatment regimen: four visits plus two interim data collection windows
- 24-week treatment regimen: four visits plus three interim data collection windows

This schedule is based on the anticipated regular follow-up for patients undergoing treatment for CHC.

Figure 1 - Study Flowchart
9.2 Setting

For overall research design and observational documentation schedule refer to Sections 9.1 and 9.4.1 as well as to Figure 1.

9.2.1 Target Population

Patients are eligible for observation in this cohort if the following applies:

- Treatment-naïve or -experienced adult male or female patients (age ≥ 18 yrs) with confirmed CHC, genotype 1 or 4, receiving combination therapy with the interferon-free ABBVIE REGIMEN ± RBV according to standard of care and in line with the current local label

- If RBV is co-administered with the ABBVIE REGIMEN, it has been prescribed in line with the current local label (with special attention to contraception requirements and contraindication during pregnancy)

- Patients must be able to speak and understand the Dutch language at such a level that they can understand and sign the informed consent and be able to understand and complete the questionnaires without any external help

- Patients must voluntarily sign and date informed consent prior to inclusion into the study

Patients are not eligible for observation in this cohort if the following applies:

- Patients participating or intending to participate in a concurrent interventional therapeutic trial

- Patients who are unable to complete the questionnaires due to cognitive impairment or lack of any kind of cognitive competence, as to be judged by the healthcare professional who is treating the patient

- Patients who are unable to complete the questionnaires due to language incompetence

- Patients who are unable to voluntarily sign and date the informed consent

- Patients included for treatment who do not meet the treatment criteria as described in the current label
9.2.2 Study Duration

This is a prospective, observational study. The inclusion period will be approximately 12 months and the observational period of the study will be from baseline visit until 24 weeks post-treatment.

The observational period for patients receiving 12 weeks of ABBVIE REGIMEN will be max. 36 weeks (12 weeks treatment and 24 weeks post-treatment observation) and for patients receiving 24 weeks of ABBVIE REGIMEN the observational period will be max. 48 weeks (24 weeks treatment and 24 weeks post-treatment observation).

9.2.3 Termination Criteria

For patients who terminate the ABBVIE REGIMEN prematurely for whatever reason the EoT eCRF page should be filled in and the reason for treatment discontinuation should be documented. If the reason for ABBVIE REGIMEN discontinuation is due to an SAE, the event must be reported to AbbVie within 24 hours of physician awareness (see Section 11.1.5).

If, in such patients, there is evidence of virological response during therapy or at EoT, the SVR12 and SVR24 pages should be completed if respective data is available.

9.2.4 Investigator Selection Criteria

University centers and outpatient clinics qualified by training and experience in the management of patients with CHC will be selected to participate in this study. The sites participating in the study should be representative of the medical practice, have the ability to conduct the study and their availability of the target patient population. The type of the participating treating institute will be documented in the eCRF.
9.3 Variables

9.3.1 Primary Variable

- The percentage of patients achieving SVR12 (HCV RNA <50 IU/mL 12 weeks [i.e. ≥70 days] after the last actual dose of the ABBVIE REGIMEN)

9.3.2 Secondary Variables

- Type of treatment regimen (± Dasabuvir, ± RBV, intended and actual combination, dose and duration)
- Adherence
  - Percentage of the DAA dose taken in relation to the target dose of DAA (cumulative dose taken divided by target dose in percent)
  - Percentage of the RBV dose taken in relation to the target dose of RBV (cumulative dose taken divided by target dose in percent)
  - Percentage of missed RBV treatment days in relation to the target number of RBV treatment days
- Serious and non-serious adverse events and pregnancy occurrences
- Questionnaires on PROs: e.g. EuroQol 5 dimension 5 level (EQ-5D-5L) questionnaire and work productivity and activity impairment (WPAI) questionnaire prior to treatment initiation, at EoT as well as 12 and 24 weeks after EoT
- Questionnaire on healthcare resource utilization

9.4 Data Sources

Source documents are defined as original documents. The investigator will document patient data in his/her own patient files which will serve as source data for the study. Data are collected from the source documents for each patient in the study, consisting of medical records containing demographic data, medical, treatment and diagnostic documentation and laboratory assessments.

The investigator(s)/institution(s) will permit study-related monitoring, audits, independent ethics committee/- review board (IEC/IRB) review, and regulatory inspection(s), providing direct access to source data documents.
9.4.1 Data to be Documented

This observational study covers three documentation periods, see Figure 1. An overview on data to be collected throughout the study is summarized in Table 2.

After the patient has signed informed consent, the following data will be documented in the eCRF, if available from the patient charts based on assessments done in physicians' routine clinical practice.

9.4.1.1 Inclusion Documentation

Inclusion:

Patients will be included only after the physician and the patient have decided to treat chronic HCV with paritaprevir/r and ombitasvir +/- dasabuvir +/- ribavirine. To guarantee independence of prescription choice of the HCP, a nurse practitioner will check if a newly prescribed patient might be eligible for the study and if so, may inform the patient about participation in the observational study.

Patients can be enrolled in the PMOS during the first 4 weeks of treatment, enabling the nurse practitioner to search eligible newly prescribed patients also from medical records.

After the patient has been found eligible and after the informed consent has been signed, the following will be documented if available:

- Demographic information
  - Interleukin 28B (IL28B) genotypes
- CHC disease characteristics
  - Year of diagnosis and mode of infection
  - Stage of liver fibrosis/cirrhosis (Annex 4)
- CHC treatment history
  - Naive or experienced
  - If experienced, most recent prior therapy and outcome
- Relevant medical history, co-morbidities and co-infections
- Concomitant medication, see 9.4.1.5
- ABBVIE REGIMEN ± RBV
Laboratory data

Key clinical chemistry
- ALT (alanine-aminotransferase) including upper limit of normal (ULN),
- AST (aspartate-aminotransferase) including ULN,
- AST to platelet ratio index (APRI) and Fibrosis-4 Score/Index (FIB-4)* will be calculated
- γ-GT (gamma-glutamyltransferase)
- Total bilirubin
- Albumin
- Creatinine creatinine clearance* will be calculated
- AFP

Key hematology
- Hb (Hemoglobin)
- Platelets
- Prothrombin time or international normalized ratio (INR)

Virology
- HCV genotype and subtype
- HCV RNA quantitative/ qualitative HCV RNA by polymerase chain reaction (PCR) test, see 9.4.1.4

HIV-infected patients only
- CD 4 count most recent assessment (cluster of differentiation 4)
- HIV RNA in copies/mL

*derived from patient’s age, ALT, AST and platelets
*by Cockcroft-Gault-Formula based on creatinine, gender, age and weight

- Patient questionnaires, see Table 2 and 9.4.1.6
- Treatment related health care resource utilization

9.4.1.2 During Treatment Documentation

Follow-up visits are scheduled by the physician per routine clinical practice. Likewise treatment, procedures and diagnostic methods will follow physicians’ routine clinical practice.
The following will be documented if available:

- **Laboratory data**
  - **Key clinical chemistry**
    - ALT including ULN
    - AST including ULN, APRI and FIB-4 will be calculated
    - γ-GT
    - Total bilirubin
    - Creatinine creatinine clearance will be calculated
  - **Key hematology**
    - Hb
    - Platelets
  - **Virology**
    - HCV RNA quantitative/ qualitative HCV RNA PCR test, see 9.4.1.4
    - HIV-infected patients only
      - CD 4 count most recent assessment
      - HIV RNA in copies/mL

- Concomitant medication, see 9.4.1.5
- Adherence to ABBVIE REGIMEN ± RBV as established by interviewing the patient during regular visits
- Tolerability (sAEs and AEs, see 11.1.5) and pregnancies (see 11.1.6)
- Patient questionnaires see 9.4.1.6
- Treatment related health care resource utilization

### 9.4.1.3 Post-Treatment Documentation

Follow-up visits are scheduled by the physician per routine clinical practice. Likewise treatment, procedures and diagnostic methods will follow physicians’ routine clinical practice.
The following will be documented:

- **Laboratory data**

  **Key clinical chemistry**
  - ALT including ULN
  - AST including ULN, APRI and FIB-4, will be calculated
  - γ-GT
  - Total bilirubin
  - Albumin
  - Creatinine creatinine clearance will be calculated

  **Key hematology**
  - Hb
  - Platelets
  - Prothrombin time or INR

  **Virology**
  - HCV RNA quantitative/ qualitative HCV RNA PCR test, see 9.4.1.4

  **HIV-infected patients only**
  - CD 4 count most recent assessment
  - HIV RNA in copies/mL

- **T tolerability (sAEs, see 11.1.4) and pregnancies (see 11.1.6)**
- **Patient questionnaires see 9.4.1.6**

Abbreviations:  
EoT = End of Treatment (at Week 12 or 24 or at premature discontinuation),  
PT = Post-Treatment  
a Written informed consent must be obtained before any data documentation in the eCRF  
b Patients who prematurely discontinue should return to the site to document EoT data  
c Healthcare professional documents the type of therapy that will be initiated (12 vs 24 wks, Paritaprevir/r – ombitasvir alone vs Paritaprevir/r – ombitasvir + dasabuvir, with or without Ribavirine depending on the genotype of the virus and disease status of the patient)  
d Tolerability documentation until PT week 4  
e Pregnancy reporting for patients treated with DAA +/- RBV (see 11.1.6)
9.4.1.4 HCV RNA Sample

HCV RNA sample – the following needs to be documented:

- **Quantitative** HCV RNA by PCR test
  - Test name and result in IU/mL
  - Lower limit of detection (LLoD) in IU/mL and lower limit of quantification (LLoQ) in IU/mL

- **Qualitative** HCV RNA by PCR test
  - Test name and result (positive/negative)
  - LLoD in IU/mL

9.4.1.5 Concomitant Medication

Concomitant medication - the following will be documented:

- Concomitant medication used from the time when the decision is made to initiate treatment with the ABBVIE REGIMEN until after the last dose

It should be verified by the treating physician that concomitant medication can be safely administered with the ABBVIE REGIMEN (including ritonavir) and RBV. Some medications may be contra-indicated, some may require dose adjustments due to potential for drug-drug interactions (DDIs). The investigator or qualified designee should review the concomitant medication(s) labels and screen concomitant medications at each visit for potential DDIs.

9.4.1.6 Standardized Assessment Tools

This study will assess quality of life and work productivity using PRO instruments: EQ-5D-5L and WPAI Hep C. Validated translations of these patient questionnaires will be administered.

**Assessment of general quality of life - EQ-5D-5L**

The EQ-5D-5L is a health state utility instrument that evaluates preference for health status (utility). The 5 items in the EQ-5D-5L comprise 5 dimensions (mobility, self-care, usual activities, pain/discomfort, and anxiety/depression) each of which are rated on 5 levels of severity. Responses to the 5 items encode a discrete health state which is
mapped to a preference (utility) specific for different societies. Patients also rate their perception of their overall health on a separate visual analogue scale (VAS).

The EQ-5D-5L should require approximately 5 minutes to complete and is presented in Annex 2.

Assessment of work productivity and activity impairment – WPAI Hep C V2.0

The WPAI questionnaire will be used to measure work absenteeism, work presenteeism, and daily activity impairment. The WPAI questionnaire was created as a patient-reported quantitative assessment of both reduced productivity at work and non-work activities. WPAI has been validated as a general health measure (WPAI-GH) and can be easily modified for specific health condition, disease or problem (WPAI-SHP). WPAI Hep C V2.0 is the HCV specific questionnaire that will be used in this study. Respondents are asked about time missed from work and time while at work during which productivity was impaired in the past seven days. Results of WPAI are expressed as a percentage of impairment from 0 to 100, with higher percentages indicating greater impairment and less productivity:

- % Presenteeism – percentage of impairment while working due to health problem
- % Absenteeism – percentage of work time missed due to health problem
- % Total work productivity impairment (TWP) – percentage of overall work impairment due to health problem
- % Total activity impairment (TAI) – percentage of general (non-work) activity impairment due to health problem

The WPAI Hep C should require approximately 5 minutes to complete and is presented in Annex 3.

PRO data are not considered a potential source of adverse reactions. However, participating sites should review the PRO data and if a possible product-related event (including a suspected adverse reaction) is noted, the health care provider (HCP) must determine whether the event is related to paritaprevir/r – ombitasvir ± dasabuvir (or any other AbbVie authorized product) and if so, it should be reported to AbbVie. The relevant AbbVie Pharmacovigilance contact details are specified in Section 11.0.
9.5 Study Size

The sample size of the study is not based on statistical considerations. It is expected that 50-55 patients can be enrolled.

9.6 Data Management

9.6.1 Electronic Case Report Forms

Data for this study will be recorded in English by each participating center via an electronic data capture (EDC) system using a web-based eCRF. Examinations, diagnostic measures, laboratory assessments, findings and observations routinely performed in patients with CHC included in this cohort, will be transcribed by the investigator or designee from the source documents into the eCRF. Only data specified in the protocol will be entered into the eCRF. For each enrolled patient, the investigator or designee will create a new patient file in the eCRF and a unique patient number will be automatically allocated by the system.

A comprehensive data validation program utilizing front-end checks in the eCRF will validate the data. Automated checks for data consistency will be implemented; discrepancies need to be solved by the researcher in the eCRF before the module can be completed.

Follow-up on eCRF data for medical plausibility will be done by AbbVie personnel (or their representatives). Queries will be generated in the eCRF for online resolution at the site. The investigator or an authorized member of the investigator's staff will make any necessary data corrections to the eCRF. All change information, including the date and person performing the corrections, will be available via the audit trail, which is part of the EDC system. The principal investigator of each site will finally review the eCRFs for completeness and accuracy of available data and provide his or her electronic signature and date to the eCRFs as evidence thereof.

Access to the EDC system will be provided for the duration of the study through a password-protected method of internet access. Such access will be removed from investigator sites at the end of the site's participation in the study. Data from the EDC system will be archived on appropriate data media (e.g. CD-ROM) and provided to the investigator as a durable record of the site's eCRF data.

Original Questionnaires will be sent from the participating site to:
9.6.2 Assignment of Preferred Terms

AEs will be coded using the Medical Dictionary for Regulatory Activities (MedDRA) and will be tabulated by primary MedDRA system organ class (SOC) and preferred term (PT). For treatments, surgical and medical procedures the international non-proprietary name (INN) Drug Terms and Procedures Dictionary will be used.

9.7 Data Analysis

9.7.1 Analysis Population, Time Windows and Handling of Missing Data

The target population (TP) is defined as all patients who fulfill the criteria specified in Section 9.2.1. The core population (CP) is defined as all patients of the TP, who have started the treatment combination recommended in the current local label for their disease characteristics. Patients not receiving the treatment recommended in the local label will be summarized in the non-core population (NCP). In addition, the core population with sufficient follow-up data (CPSFU) is defined as all CP patients, who fulfil one of the following criteria:

1. evaluable HCV RNA data ≥70 days after the last actual dose of the ABBVIE REGIMEN (i.e. data within the SVR12 time window)

2. a HCV RNA value ≥50 IU/mL at the last measurement post-baseline (i.e. no virological response achieved at the last measurement on-treatment or post-treatment)

3. HCV RNA <50 IU/mL at the last measurement post-baseline, but no HCV RNA measurement ≥70 days after the last actual dose of the ABBVIE REGIMEN due to reasons related to safety (e.g. dropped out due to AE) or incomplete efficacy information (e.g. virologic failure such as relapse is reported in the eCRF but date and value of the corresponding HCV RNA test is missing). This means only patients who had virological response at their last on-treatment or post-treatment
measurement, but had no HCV RNA measurements ≥70 days post-treatment for reasons not related to safety or effectiveness (e.g. lost-to-follow-up or patient not willing to perform an additional HCV RNA test ≥70 days post-treatment) will be excluded from this analysis.

The Safety Population (SP) is defined as all patients who received at least one dose of the ABBVIE REGIMEN.

In accordance with the non-interventional nature of the study all HCV RNA measurements will be performed at the sole discretion of the physician and all HCV RNA measurements have to be entered into the eCRF. All recorded HCV RNA values will be assigned to appropriate time points (baseline, on-treatment visits, EoT visit, post-treatment visits). The time windows for the assignments will be specified in the statistical analysis plan (SAP).

No data will be imputed for any effectiveness or safety analyses except for the analyses of the HCV RNA endpoints. When there is no HCV RNA value in a visit time window post-baseline, but prior to EoT, the closest values before and after the window, regardless of the value chosen for the subsequent and preceding window, will be used for the flanking imputation described below. If a patient has a missing HCV RNA value at a post-baseline visit prior to EoT but has undetectable HCV RNA (with LLoD ≤50 IU/mL) or unquantifiable, but detectable HCV RNA levels (with LLoQ ≤50 IU/mL) at both the preceding and succeeding measurements, the HCV RNA level will be considered undetectable or unquantifiable, respectively, at this visit for this patient. In addition, if a patient has an unquantifiable HCV RNA level at the preceding measurement and an undetectable HCV RNA level at the succeeding measurement, or vice versa, the HCV RNA level will be imputed as unquantifiable at this visit for this patient. For virological response at EoT a corresponding backward imputation approach will be applied. This means if HCV RNA is missing at EoT, then unquantifiable or undetectable will be assumed for EoT, if the succeeding HCV RNA value is undetectable or unquantifiable. For SVR12 the single last available HCV RNA measurement ≥70 days post-treatment will be used. Subsequent to this flanking and backward imputation, if the HCV RNA value remains missing at a specific time point, then the patients will considered as virological failure at this time point (i.e. not undetectable or unquantifiable).

9.7.2 Demographics and Disease Characteristics

All baseline and disease characteristics will be summarized for the CP stratified by the CP analysis groups (i.e. based on genotype 1 subtype, fibrosis status, treatment
experienced or naive), which are relevant for scheduled treatment combination (ABBVIE REGIMEN ± RBV) and duration (12 and 24 weeks). In addition, baseline summaries will be repeated for the SP and the TP without stratification into subgroups. Summary statistics (n, mean, median, standard deviation [SD] and range will be generated for continuous variables (e.g. age and body mass index [BMI]). The number and percentage of patients will be presented for categorical variables (e.g. gender). Further details of analysis populations and the CP analysis groups will be specified in the SAP, taking into account the ABBVIE REGIMEN recommended in the current local label for various patient groups.

9.7.3 Effectiveness Analysis

The primary effectiveness analysis on clinical outcomes will be performed on all patients in the CP stratified by the CP analysis groups. Due to the non-interventional nature of this study several different methods for determination of the HCV RNA value can be applied. For the purpose of the statistical analysis, a HCV RNA measurement is considered ≤50 IU/mL,

- if a PCR test was used
- and the test result is undetectable and the LLoD of the test is ≤50 IU/mL or the test result is unquantifiable and the LLoQ is ≤50 IU/mL

9.7.3.1 Primary Effectiveness Endpoint

The percentage of patients achieving SVR12 (single last HCV RNA <50 IU/mL 12 weeks [i.e. at least 70 days] after the last actual dose of the ABBVIE REGIMEN) is the primary effectiveness endpoint.

9.7.3.2 Secondary Effectiveness Endpoints

The secondary effectiveness endpoints are:

- The percentage of patients with virological response (HCV RNA <50 IU/mL) at EoT
- The percentage of patients with relapse (defined as HCV RNA <50 IU/mL at EoT followed by HCV RNA ≥50 IU/mL)
• The percentage of patients with breakthrough (defined as at least one documented HCV RNA <50 IU/mL followed by HCV RNA ≥50 IU/mL during treatment).

• The number and percentage of patients meeting each and any of the following SVR12 non-response categories:
  o On-treatment virologic failure (breakthrough [defined as above] or failure to suppress [each measured on-treatment HCV RNA value ≥50 IU/mL])
  o Relapse (defined as HCV RNA <50 IU/mL at EoT or at the last on-treatment HCV RNA measurement followed by HCV RNA ≥50 IU/mL post-treatment)
  o Premature study drug discontinuation with no on-treatment virologic failure
  o Missing SVR12 data and/or none of the above criteria

9.7.3.3 Statistical Methods for Analysis of Effectiveness Variables

The simple percentage of patients achieving SVR12 will be calculated and an exact two-sided 95% confidence interval (CI) of the percentage will be computed based on the Wilson’s Score method.

Corresponding methods will be used for other response rates (EoT response rate, relapse rate, viral breakthrough). The relapse rates will be estimated in patients of the CP analysis groups with EoT response and sufficient HCV RNA measurements post-treatment. Viral breakthrough rates will be estimated in all patients of the CP analysis groups, who have at least one undetectable HCV RNA measurement on-treatment and at least one on-treatment or EoT measurement thereafter.

Univariate logistic regression methods will be used to investigate the impact of the following explanatory covariates on SVR12:

• Key demographic information
• Mode of CHC infection
• HCV RNA level at baseline
• Most recent stage of liver fibrosis
• HCV genotype and subtype (if available)
• Type of treating institute
• Liver and/or CHC related co-morbidities
• Key clinical chemistry and hematology laboratory variables at baseline
In treatment experienced patients only:
  - Most recent prior treatment for CHC
  - Outcome of most recent prior CHC treatment

Further details and additional covariates will be specified in the SAP.

These analyses will be of exploratory nature, data driven, and will be repeatedly performed for various CP Analysis Groups, since not each covariate might be predictive in each patient group. Logistic regression methods will also be used to investigate the impact of treatment adherence on SVR12.

### 9.7.4 Clinical Laboratory Data

All reported clinical laboratory test results will be assigned to one of the time points using the time windows specified in the table below.

#### Table 4 - Analysis Time Windows

</tbody>
</table>

Mean changes from baseline to each post-baseline visit will be summarized descriptively.
Laboratory data values collected during the treatment period will be categorized as low, normal, or high based on reference ranges used in this study. The number and percent of patients who experience post-baseline shifts during treatment in clinical laboratory values from low/normal to high and high/normal to low based on the reference range will be summarized.

Additional details of the analyses of clinical laboratory data will be specified in the SAP.

### 9.7.5 Patient Questionnaires

The EQ-5D-5L is a health state utility instrument that evaluates preference for health status (utility). The EQ-5D-5L comprises 5 dimensions (mobility, self-care, usual activities, pain/discomfort, anxiety/depression) each of which are rated on 5 levels of severity (1: indicating no problem, 2: indicating slight problems, 3: indicating moderate problems, 4: indicating severe problems, 5: indicating extreme problems), and a separate VAS.

Patients’ responses to the EQ-5D-5L will be combined into a unique health state using a 5-digit code with one digit from each of the 5 dimensions representing the level of severity. These EQ-5D-5L states will be converted into a single preference-weighted health utility index score by applying country-specific weights (if available) or US weights (if not available).

No imputation will be performed for missing items, and in case of missing items no index score will be calculated.

A summary table will show descriptive statistics (n, mean, median, SD, minimum and maximum) of the index score values and for the VAS values for baseline and the post-baseline time points, as well as changes from baseline both for the index score values and for the VAS values.

Assessments of work productivity and activity impairment as assessed by the WPAI Hep C v2.0 will be evaluated according to the WPAI-SHP scoring manual. The WPAI yields four types of scores, the results of which will be presented as percentage of impairment from 0 to 100. Higher percentages indicate greater impairment:

1. % absenteeism: percentage of work time missed due to hepatitis C
2. % presenteeism: percentage of impairment while working due to hepatitis C
3. % TWP: percentage of overall work impairment due to hepatitis C
4. % TAI: percentage of general (non-work) activity impairment due to hepatitis C
The WPAI Hep C v2.0 consists of 6 questions aimed at the following targets:

Q1. currently employed (yes, no)
Q2. hours missed due to hepatitis C in the last seven days
Q3. hours missed due to other reasons in the last seven days
Q4. hours actually worked in the last seven days
Q5. degree hepatitis C affected productivity while working
Q6. degree hepatitis C affected regular activities

The four scores will be derived as follows:

1. % absenteeism: 100*Q2/(Q2+Q4)
2. % presenteeism: 100*Q5/10
3. % TWP: 100*{Q2/(Q2+Q4) + [Q4/(Q2+Q4)]* Q5/10}
4. % TAI: 100*Q6/10

A score will be set to missing if one or more of the items Q1-Q6 that are needed for the calculation of the score are missing. No imputation will be performed for missing items.

The summary table will present the absolute and relative frequencies of employed and unemployed patients and descriptive statistics for the four scores. Further details of the analysis will be specified in the SAP.

9.7.6 Tolerability Analysis

All tolerability variables will be summarized using descriptive statistical methods for the SP stratified by type of combination treatment and scheduled treatment duration.

All SAEs, non-serious AEs and pregnancy occurrences are to be reported for patients included in the study (see Section 11.0 and 9.2.3). AEs will be coded using MedDRA. The number and percentage of patients with treatment-emergent AEs (i.e. any reported event that begins or worsens in severity after initiation of study drug through 30 days post-study drug dosing) will be tabulated by primary MedDRA SOC and PT.

Corresponding summary tables will be provided for all serious treatment-emergent AEs. The tabulation of the number of patients with treatment-emergent AEs by severity and relationship to study drug will also be provided. Patients reporting more than one AE for a given MedDRA PT will be counted only once for that term using the most severe incident for the severity summary table and the most related for the relationship summary table. Patients reporting more than one type of event within a SOC will be counted only once for that SOC.
Additional details of the analysis of AEs will be specified in the SAP.

### 9.7.7 Interim Assessments

An interim assessment is planned at 12 months (or when 50% of target population has achieved SVR12) after first patient in, details will be specified in the SAP.

### 9.8 Quality Control

The sites will be instructed in the protocol, the functionality and handling of the eCRF, and the requirement to maintain source documents for each patient in the study (see Section 9.4).

A comprehensive data validation program utilizing front-end checks in the eCRF will validate the data. Automated checks for data consistency will be implemented, discrepancies need to be solved by the researcher in the eCRF before the module can be completed. Follow-up on eCRF data for medical plausibility will be done by AbbVie personnel (or their representatives). The principal investigator of each site will finally review the eCRFs for completeness and accuracy of available data and provide his or her electronic signature and date to eCRFs as evidence thereof.

Continuous monitoring of the study and frequent site telephone contacts will be done by AbbVie or a CRO working on behalf of AbbVie.

### 9.9 Limitations of the Research Methods

The limitations of observational studies, such as uncontrolled confounding by lack of randomization, and difficulties to clearly interpret treatment effects in the context of missing data are well known. Their validity can be increased by accurate outcome measurements, documentation of the most common confounders, sufficient length of follow-up and by activities to obtain complete recording of available data as well as by searches for missing key data.

The most important outcome measure in this study is HCV RNA. Missing or unrecorded follow-up HCV RNA data can in particular lead to an underestimation of the real SVR rate as compared to the SVR rate of interventional trials. Highly sensitive and quantitative diagnostic tests are required to measure HCV RNA levels in blood. In an observational
study each center will be using its own test – either commercially available or so-called “home-brew” tests – which might change from one visit to the next within a patient data set. The challenge is to accurately and consistently document test properties such as the LLoD and the LLoQ to put the results into perspective of prior outcomes from randomized controlled trials with (usually) central laboratory assessments for all trial participants.

10.0 Protection of Human Subjects

This observational study will be run in compliance with local laws and regulations. Notification/submission to the responsible regulatory authorities, Ethics Committee (EC) and/or Competent Authorities (CAs) will be done as required by local laws and regulations.

The investigator is responsible to ensure that written informed consent will be obtained prior to patient inclusion.

To maintain patient confidentiality, no demographic data that can identify the patient will be collected (e.g. initials, date of birth) - only the patient age will be collected. In order to protect patient identity, a unique number will be assigned to each patient and related study recording.

11.0 Management and Reporting of Complaints

A Complaint is any written, electronic, or oral communication that alleges deficiencies related to the physical characteristics, identity, quality, purity, potency, durability, reliability, safety, effectiveness, or performance of a product/device after it is released for distribution.

Complaints associated with any component of the ABBVIE REGIMEN must be reported to the Sponsor (Section 11.2.2).

For adverse events, please refer to Sections 11.1.1 through 11.1.6. For product complaints, please refer to Section 11.2.
11.1 Medical Complaints

PRO data are not considered a potential source of adverse reactions. However, participating sites should review the PRO data and if a possible product-related event (including a suspected adverse reaction) is noted, the HCP must determine whether the event is related to the ABBVIE REGIMEN ± RBV (or any other AbbVie authorized product) and if so, it should be reported to AbbVie.

Medication errors (this refers to any unintentional error in the prescribing, dispensing, or administration of a medicinal product while in control of the HCP, patient or consumer) should be reported by the HCP to AbbVie.

The relevant AbbVie Pharmacovigilance contact details are specified below:

11.1.1 Adverse Event Definition and Serious Adverse Event Categories

An adverse event (AE) is defined as any untoward medical occurrence in a patient, which does not necessarily have a causal relationship with their treatment. An AE can therefore be any unfavorable and unintended sign (including an abnormal laboratory finding), symptom, or disease temporally associated with the use of a medicinal product, whether or not the event is considered causally related to the use of the product.

Such an event can result from use of the drug as stipulated in the labeling, as well as from accidental or intentional overdose, drug abuse, or drug withdrawal. Any worsening of a pre-existing condition or illness is considered an AE.

If an AE meets any of the following criteria, it is considered a serious adverse event (SAE):

- **Death of Patient:** An event that results in the death of a patient.
- **Life-Threatening:** An event that, in the opinion of the investigator, would have resulted in immediate fatality if medical
intervention had not been taken. This does not include an event that would have been fatal if it had occurred in a more severe form.

**Hospitalization:**
An event that results in an admission to the hospital for any length of time. This does not include an emergency room visit or admission to an outpatient facility.

**Prolongation of Hospitalization:**
An event that occurs while the study patient is hospitalized and prolongs the patient’s hospital stay.

**Congenital Anomaly:**
An anomaly detected at or after birth, or any anomaly that results in fetal loss.

**Persistent or Significant Disability/Incapacity:**
An event that results in a condition that substantially interferes with the activities of daily living of a study patient. Disability is not intended to include experiences of relatively minor medical significance such as headache, nausea, vomiting, diarrhea, influenza, and accidental trauma (e.g. sprained ankle).

**Important Medical Event Requiring Medical or Surgical Intervention to Prevent Serious Outcome:**
An important medical event that may not be immediately life-threatening or result in death or hospitalization, but based on medical judgment may jeopardize the patient and may require medical or surgical intervention to prevent any of the outcomes listed above (i.e. death of patient, life threatening, hospitalization, prolongation of hospitalization, congenital anomaly, or persistent or significant disability/incapacity). Additionally, any elective or spontaneous abortion or stillbirth is considered an important medical event. Examples of such events include allergic bronchospasm requiring intensive treatment in an emergency room or at home, blood dyscrasias or convulsions that do not result in inpatient hospitalization, or the development of drug dependency or drug abuse.
11.1.2 Severity

The following definitions will be used to rate the severity for any AE being collected as an endpoint/data point in the study and for all SAEs.

**Mild:** The AE is transient and easily tolerated by the patient.

**Moderate:** The AE causes the patient discomfort and interrupts the patient's usual activities.

**Severe:** The AE causes considerable interference with the patient's usual activities and may be incapacitating or life threatening.

11.1.3 Relationship to Pharmaceutical Product

The following definitions will be used to assess the relationship of the AE to the use of product:

**Reasonable Possibility** An AE where there is evidence to suggest a causal relationship between the product and the AE.

**No Reasonable Possibility** An AE where there is no evidence to suggest a causal relationship between the product and the AE.

If no reasonable possibility of being related to product is given, an alternate etiology must be provided for the AE.

11.1.4 Serious Adverse Event Collection Period

SAEs will be reported to AbbVie from the time the physician obtains the informed consent until 30 days or 5 half-lives following the intake of the last dose of physician-prescribed treatment.

11.1.5 Serious and non-serious Adverse Event Reporting

In the event of an SAE, the physician will:

- For events from patients using the ABBVIE REGIMEN ± RBV (or any other AbbVie authorized product) report to AbbVie within 24 hours of the physician.
becoming aware of the event by using the eCRF system or notifying the AbbVie contact person identified in Section 11.0.

- For events from patients using a non-AbbVie product - notify the Marketing Authorization Holder (MAH) of the product within 24 hours of the physician becoming aware of the event.

In the event of a **non-serious AE**, the physician will:

- For events from patients using the ABBVIE REGIMEN ± RBV report to AbbVie by using the eCRF system.

### 11.1.6 Pregnancy Reporting

Patients and their partners should avoid pregnancy and males should avoid sperm donation throughout the course of the HCV treatment and for 30 days after the end of treatment with DAAs only, or for 7 months after the last dose of RBV (or per local RBV label) and/or consistent with local treatment guidelines for RBV.

In the event of a pregnancy occurrence in the patient, the physician will report to AbbVie within 24 hours of the physician becoming aware of the pregnancy by using the eCRF system or notifying the AbbVie contact person identified in Section 11.0.

The investigator is encouraged to report the pregnancy information to the voluntary RBV Pregnancy Registry, if RBV is included within the regimen.
Section 11.2 Product Complaint

11.2.1 Definition
A Product Complaint is any Complaint (see Section 11.0 for the definition) related to the drug or drug component of the product or to the medical device component(s). For a product this may include, but is not limited to, damaged/broken product or packaging, product appearance whose color/markings do not match the labeling, labeling discrepancies/inadequacies in the labeling/instructions (example: printing illegible), missing components/product, device not working properly, or packaging issues.

11.2.2 Reporting
The relevant AbbVie Product Complaint contact details are specified below:
Name: AbbVie Regulatory Affairs & Quality Assurance

Product Complaints concerning the ABBVIE REGIMEN must be reported to the Sponsor within 24 hours of the study site’s knowledge of the event via local Product Complaint reporting practices. Product Complaints occurring during the study will be followed-up to a satisfactory conclusion. All follow-up information is to be reported to the Sponsor (or an authorized representative) and documented in source as required by the Sponsor. Product Complaints associated with adverse events will be reported in the study summary. All other complaints will be monitored on an ongoing basis. Product complaints involving a non-Sponsor investigational product and/or device should be reported to the identified contact or manufacturer, as necessary per local regulations. Product Complaints may require return of the product with the alleged complaint condition. In instances where a return is requested, every effort should be made by the investigator to return the product within 30 days. If returns cannot be accommodated within 30 days, the site will need to provide justification and an estimated date of return. The description of the complaint is important for AbbVie in order to enable AbbVie to investigate and determine if any corrective actions are required.
12.0 Plans for Disseminating and Communicating Study Results

At the end of this observational study, a report will be written by AbbVie or a CRO working on behalf of AbbVie. The required standard study report template will be followed. This report will contain a description of the objectives of the study, the methodology and its results and conclusions. The completed eCRFs, patient questionnaires, interim assessments, the final study output and study report are the confidential property of AbbVie and may not be released to unauthorized people in any form (publications or presentations) without express written approval from AbbVie. The study results will be submitted to local authorities by the participating countries per local laws and regulations.

The results of this study will be made publicly available on one of the primary registries in the World Health Organization (WHO) Registry Network which meet the requirements of the ICMJE (International Committee of Medical Journal Editors) and through scientific publications. Authorship will be in line with ICMJE' authorship requirements [68].

Deviations for:
On treatment - Early treatment (if applicable),
On treatment - Week 12 (only for patients receiving 24 weeks of therapy),
End of treatment:

Outpatient Consultation(s) - Resource Utilization (since last visit)

Outpatient consultation(s) since last visit:

. Please document for each outpatient consultation since last visit the technical interventions performed and the symptoms treated.

. Technical Intervention(s) performed

. Symptom(s) treated

. Adverse Events:
If any of the treated symptoms is an Adverse Event, please report this Adverse Event additionally in the unscheduled records section.
Hospitalization period(s) - Resource Utilization (since last visit)

Hospitalization period(s) since last visit:

Please document for each hospitalization period since last visit the number of hospitalization days, the technical interventions performed and the symptoms treated.

- Duration

  Technical Intervention(s) performed

  Symptom(s) treated

Adverse Events:
If any of the treated symptoms is an Adverse Event, please report this Adverse Event additionally in the unscheduled records section.

Serious Adverse Events:
Each unplanned hospitalization during therapy or within 30 days thereafter is considered to be an SAE and must be reported additionally on an Adverse Event page in the unscheduled records section.
### Annex 2. EQ5D-5L

Under each heading, please tick the ONE box that best describes your health TODAY

#### MOBILITY
- I have no problems in walking about [ ]
- I have slight problems in walking about [ ]
- I have moderate problems in walking about [ ]
- I have severe problems in walking about [ ]
- I am unable to walk about [ ]

#### SELF-CARE
- I have no problems washing or dressing myself [ ]
- I have slight problems washing or dressing myself [ ]
- I have moderate problems washing or dressing myself [ ]
- I have severe problems washing or dressing myself [ ]
- I am unable to wash or dress myself [ ]

#### USUAL ACTIVITIES (e.g. work, study, housework, family, or leisure activities)
- I have no problems doing my usual activities [ ]
- I have slight problems doing my usual activities [ ]
- I have moderate problems doing my usual activities [ ]
- I have severe problems doing my usual activities [ ]
- I am unable to do my usual activities [ ]

#### PAIN / DISCOMFORT
- I have no pain or discomfort [ ]
- I have slight pain or discomfort [ ]
- I have moderate pain or discomfort [ ]
- I have severe pain or discomfort [ ]
- I have extreme pain or discomfort [ ]

#### ANXIETY / DEPRESSION
- I am not anxious or depressed [ ]
- I am slightly anxious or depressed [ ]
- I am moderately anxious or depressed [ ]
- I am severely anxious or depressed [ ]
- I am extremely anxious or depressed [ ]

We would like to know how good or bad your health is TODAY.

This scale is numbered from 0 to 100.

100 means the **best** health you can imagine.
0 means the **worst** health you can imagine.

Mark an X on the scale to indicate how your health is TODAY.

Now, please write the number you marked on the scale in the box below.

YOUR HEALTH TODAY = [ ]
Annex 3. WPAI

Work Productivity and Activity Impairment Questionnaire Hepatitis C, V2.0 (WPAI: Hepatitis C)

The following questions ask about the effect of your hepatitis C on your ability to work and perform normal daily activities. Please fill in the blanks or circle a number, as indicated.

1) Are you currently in paid employment? _____ NO _____ YES
   If NO, tick "NO" and skip to question 6.

The next questions refer to the past seven days, not including today.

2) During the past seven days, how many hours did you miss from work because of problems associated with your hepatitis C? Include hours you missed on sick days, times you went in late, left early, etc., because of your hepatitis C. Do not include time you missed to participate in this study.
   _____ HOURS

3) During the past seven days, how many hours did you miss from work because of any other reason, such as annual leave, holidays, time off to participate in this study?
   _____ HOURS

4) During the past seven days, how many hours did you actually work?
   _____ HOURS (If "0", skip to question 6.)
5. During the past seven days, how much did hepatitis C affect your productivity while you were working?

Think about days you were limited in the amount or kind of work you could do, days you accomplished less than you would like, or days you could not do your work as carefully as usual. If hepatitis C affected your work only a little, choose a low number. Choose a high number if hepatitis C affected your work a great deal.

Consider only how much hepatitis C affected productivity while you were working.

Hepatitis C had no effect on my work

CIRCLE A NUMBER

Hepatitis C completely prevented me from working

6. During the past seven days, how much did your hepatitis C affect your ability to perform your normal daily activities, excluding your job?

By normal activities, we mean the usual activities you perform, such as working around the house, shopping, childcare, exercising, studying, etc. Think about times you were limited in the amount or kind of activities you could perform and times you accomplished less than you would like. If hepatitis C affected your activities only a little, choose a low number. Choose a high number if hepatitis C affected your activities a great deal.

Consider only how much hepatitis C affected your ability to perform your normal daily activities, excluding your job.

Hepatitis C had no effect on my daily activities

</tbody>
</table>

* None.
  Slight ascites = Ascites detectable only by ultrasound examination.
  Moderate ascites = Ascites manifested by moderate symmetrical distension of the abdomen.
  Severe ascites = Large or gross ascites with marked abdominal distension.

** Grade 0: normal consciousness, personality, neurological examination, electroencephalogram.
Grade 1: restless, sleep disturbed, irritable/agitated, tremor, impaired handwriting, 5 cps waves.
Grade 2: lethargic, time-disoriented, inappropriate behavior, asterixis, ataxia, slow triphasic waves.
Grade 3: somnolent, stuporous, place-disoriented, hyperactive reflexes, rigidity, slower waves.
Grade 4: unarousable coma, no personality/behavior, decerebrate, slow 2 to 3 cps delta activity
